This article from Beskow and Carley discusses the field of social cybersecurity, a concept in which the human factor is the primary focus to prevent malicious intent on the internet. Social cybersecurity is the study of humans and the relation to why we do what we do when faced with specific tasks on the internet. The goal of social cybersecurity is to shine a light on methods that we see daily and how malicious users can coerce them to fool us into thinking it's something else. In the end, the authors show ways we can be more aware of these methods to prevent malicious attacks.
