DNA testing services have become popular recently as people are curious about new technology and how it works. People are always curious about their genetic makeup but want to have a more accurate way of finding out using DNA testing. Many people find out about their genetics through their parents or ancestors. Using a DNA service allows them to get a more in-depth reading of their genetic makeup. This article talks about how these services could put a person's DNA at risk. When the company receives the DNA, the person's information is imported into a database. When a person sends the DNA samples to the company, they are not aware of what the company does with the information they have provided. If the company's database were to get hacked, this would put everyone at risk who was using the DNA testing service. These hackers could use the DNA and post it on the market to sell for money. They could also use the DNA for personal use and impersonate someone else. This article states that companies need to implement better security to keep up with the advancement of technology. Hackers will always continue to find new ways to be able to gain control of a database and test a company's security system. Companies could implement a better security system that requires authentication to be able to access the database. This ensures that data being uploaded is more secure. Companies also need to build a strong security system to make sure if the database is hacked, they are able to regain control of the database as well as recover all information that was stolen or compromised.
