

The article I chose was about cyber security working from home during COVID-19. This article relates to the principles of social science in multiple ways. The first thing I noticed was the article was straightforward explanations and nothing dragged out which relates to parsimony. Next this topic relates to empiricism, as it deals with covid - 19 and its real senses. Lastly, determinism relates to this topic the most as it explains how covid affected millions of people which caused lots to work from home. This study was about working from home during lockdown and how both the logical factors affected the employee's cybersecurity practices. The method used for this study was interpretative phenomenological analysis and it concentrates on how the individuals make sense of their world and what that experience means for them. This process has 4 different stages that make up the method. The concept from class that relates to this article is the determinism models, precisely the Nomothetic model. I say this because in the article there is a table which shows the five different themes and a few causes of each one and in the Nomothetic model it identifies the relatively few causes of a behavior. The way this topic relates to the challenges of marginalized groups because everyone works different for example introverts prefer to work at home alone as it makes them more comfortable than being in an office with others. The concern of marginalized groups is sometimes the sample size is not big enough to come up with a conclusion. This article shows contributions of marginalized groups by not generalizing and using actual logic.
